Problem

Accurate Risk Assessment – real time and static

- **Complex physics** and uncertainty demand high fidelity computational models
- Physics-based models are **expensive** and can be infeasible
- Physics are routinely limited
- Climate forecasts can change rapidly and frequently
- Need to **understand uncertainty**
- Want flexibility - Stakeholders perspectives change AFTER modeling is complete, hazards of concern may shift (e.g. vary scenarios, climate change)

Specific Objectives

- **High-fidelity Surrogate Models** for Hurricane Response
 - ▶ Rapid prediction of response: inundation (surge+tide), wave height, wave period, wave direction, currents, wind speed, wind direction
 - ▶ NOAA and Coastal Hazards System data linkage
 - ▶ Robust surrogate parameterization
 - ▶ Uncertainty
- **Centralized computation/distribution - Coastal Hazards System**
- **Stand-alone PC software - CHRPS**

Nearshore Processes are Complex

3M nodes, min res ~20 m.

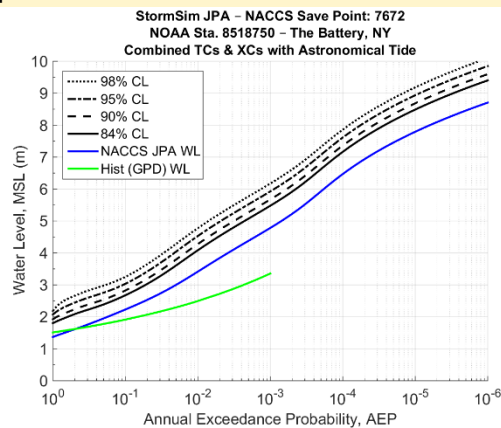

Parameterization of Tropical Cyclones

HURDAT database – 1851-present

TS are rare so extreme responses not well represented in measurements

Tropical Storms can be parameterized

$$\text{Response} = f(\hat{x}) = f(X_0, DP, R_{\max}, V_f, q)$$

X_0 = Land fall location (lat, lon)

θ = Angle of storm approach

ΔP = Minimum central pressure

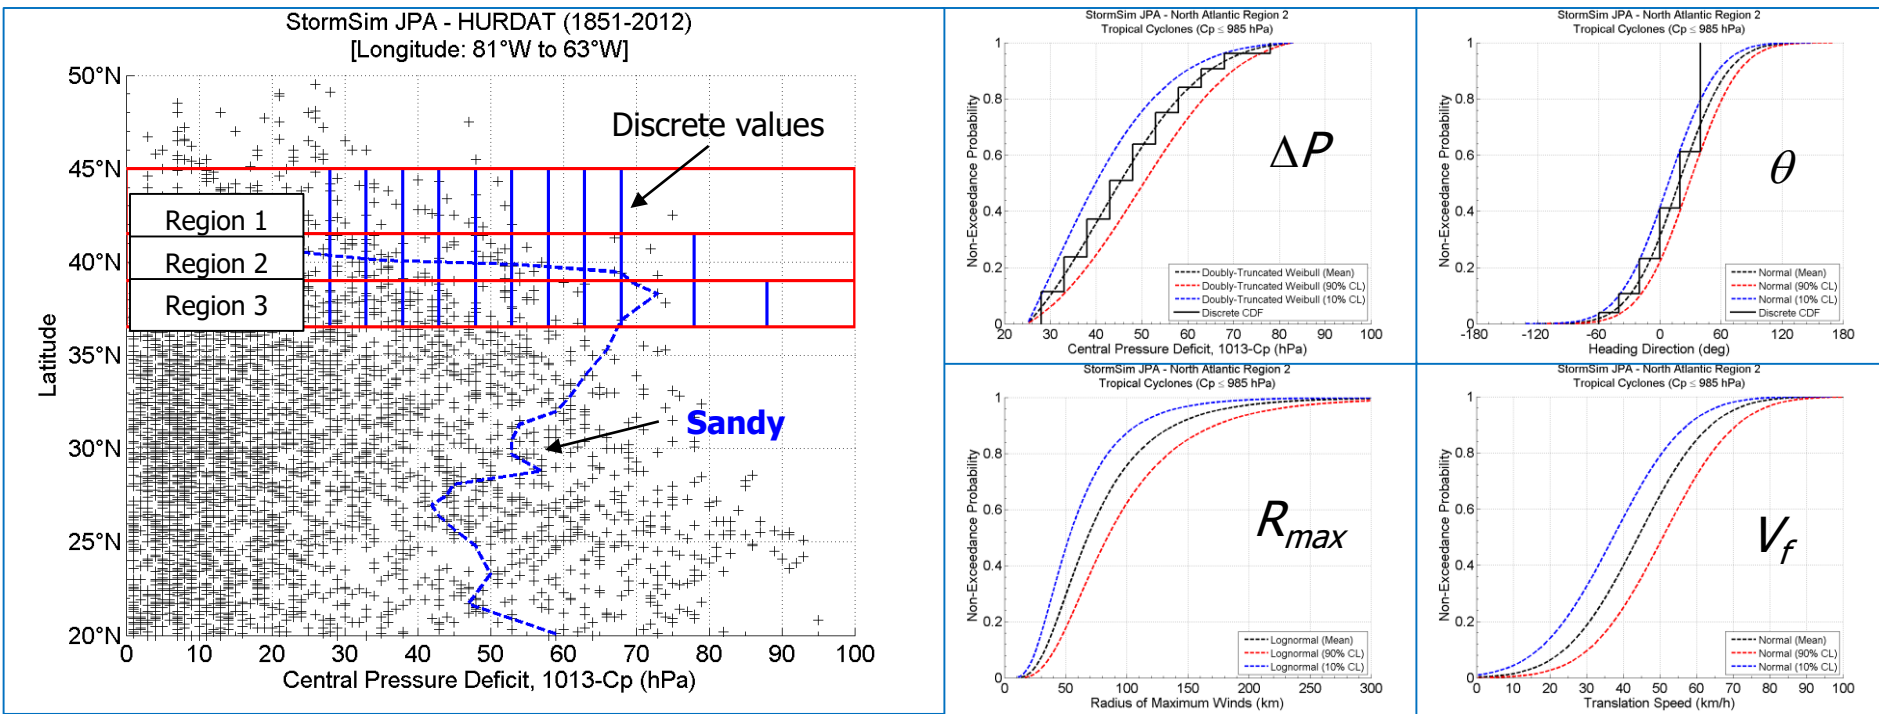

V_f = Average forward speed

R_{\max} = Radius of maximum winds

Parameterization of Tropical Cyclones

Non-Exceedance Probability Distributions

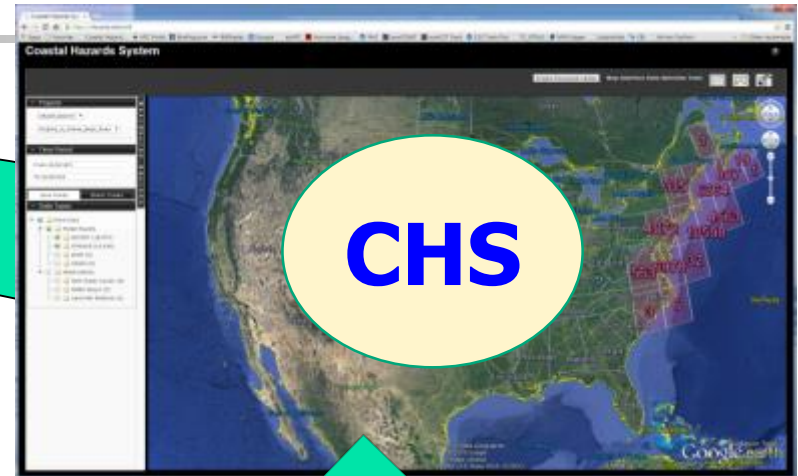

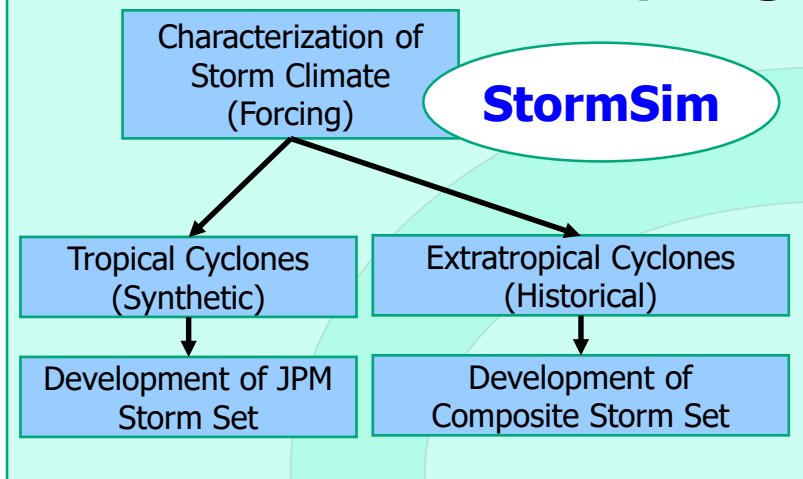

$$\text{Response} = f(\hat{x}) = f(X_0, DP, R_{\max}, V_f, q)$$

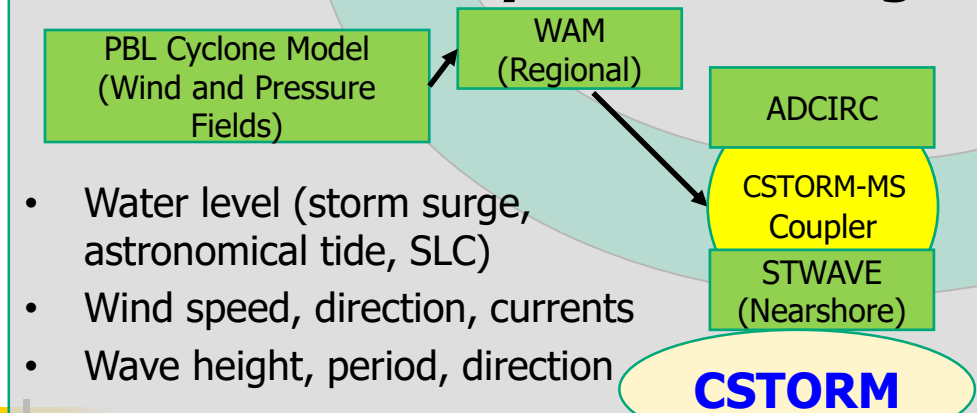

Hybrid Discretization: Uniform: $\theta, \Delta P$; Bayesian Quadrature: R_{\max}, V_f

Coastal Hazards System

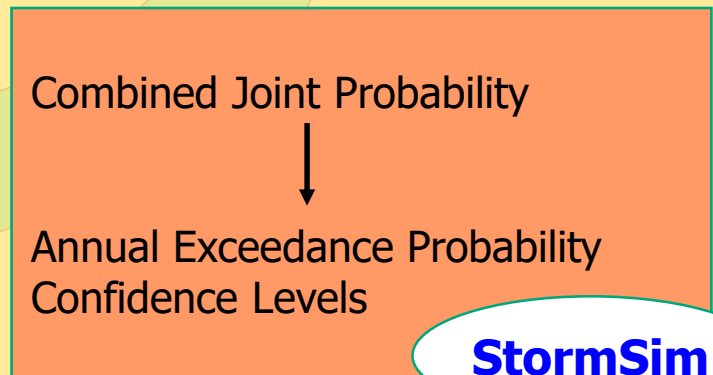

Efficient Storm Sampling

Climate and Hydro Modeling

Response Statistics

Storm Screening

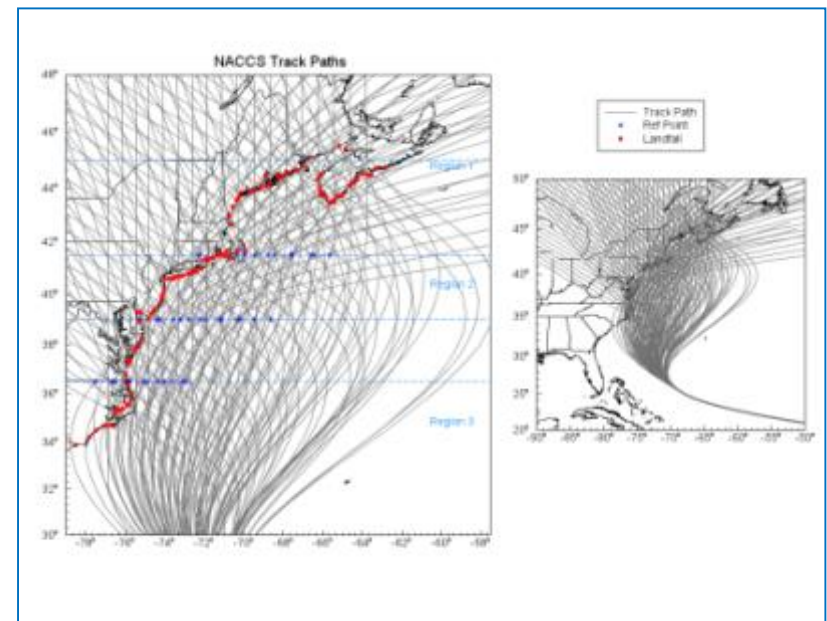

TX/LA/MS/AL/FL – 1187 storms

- C_p : 900 - 975 mb
- $V_{\dot{f}}$: 11 – 33 km/hr
- R_{max} : 11 – 51 km

NACCS – 1150 storms

- C_p : 915 – 985 mb
- $V_{\dot{f}}$: 12 – 88 km/hr
- R_{max} : 25 – 174 km

Surrogate Modeling

Surrogate Techniques: Data Driven

- Least squares regression
- Low dimensional spline interpolation
- Dimensional functions
- Polynomial chaos
- Response surface approximations
- **Artificial neural networks**
- **Kriging or Gaussian process emulation**

Gaussian Process Emulator

Want $f(x_1), \dots, f(x_N)$, but only know $f(x_1), \dots, f(x_n)$, for $n \ll N$.
Need to quantify uncertainty in the estimate?

A statistical inference problem:

Derive a probability distribution for f given $f(x_1), \dots, f(x_n)$ (an “emulator”)

Popular technique: Gaussian process emulation (Sacks et al. 1989)

Assume $f(x) = m(x) + Z(x)$

$m(x)$ is a parametric function of x (linear, quadratic, spline, ...)

Z is a zero mean Gaussian process (the deviation of $f(x)$ from m)

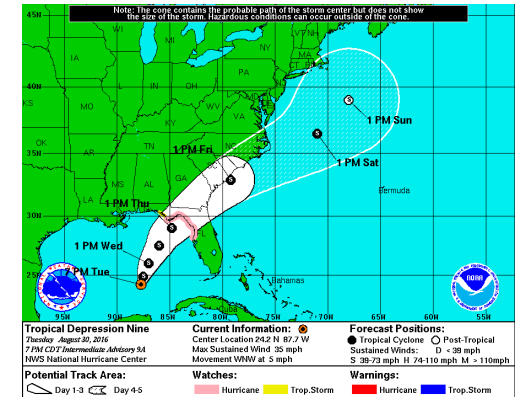

Z is specified with its covariance where the variance σ^2 suggests how far $f(x)$ deviates from $m(x)$

Surrogate Modeling

Inputs

- **Forcing**, input vector \mathbf{x}
 - Land fall location (lat, lon)
 - Landfall angle of storm approach
 - Minimum central pressure (e.g. 90 nm)
 - Landfall forward speed
 - Radius of maximum winds (e.g. 90 nm)

Outputs

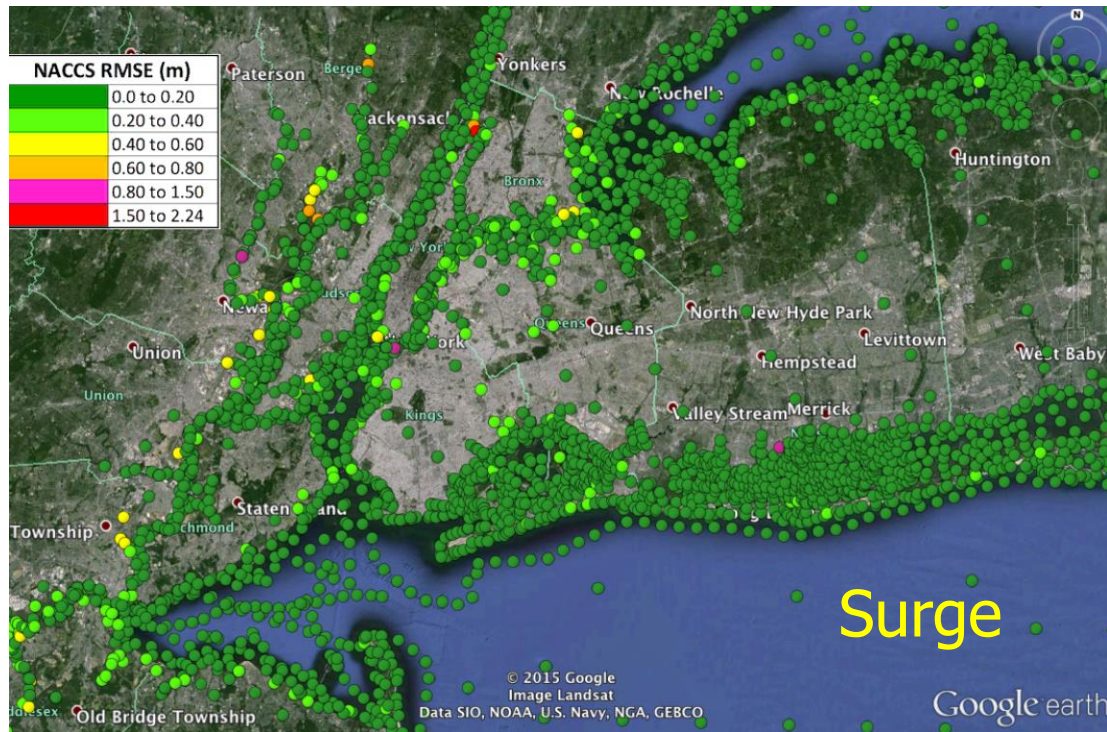

- **Response:** Storm **surge, wave height, wave period**, wave direction, wind speed, wind direction, currents over region

Augment data with dry node information

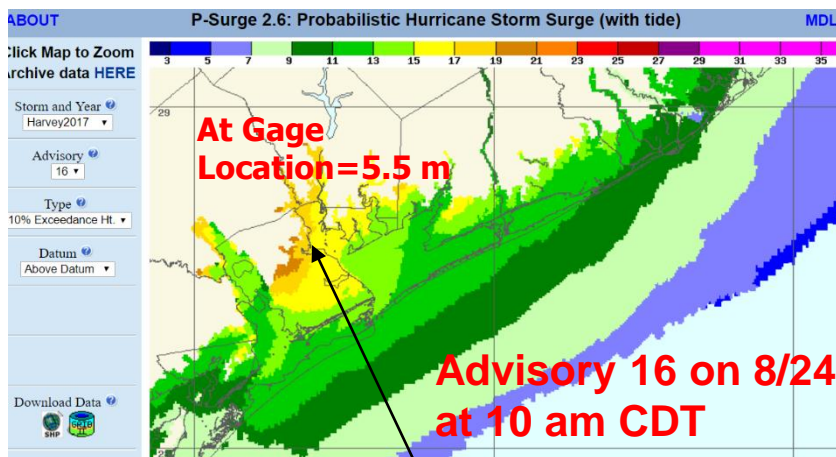

Reduce dimensionality - Perform PCA to obtain latent space, retain 99.9% of variance – for LA/MS retained ~40 PCs for model trained on peaks and 100 for model trained on time series

New York Bight LOOCV

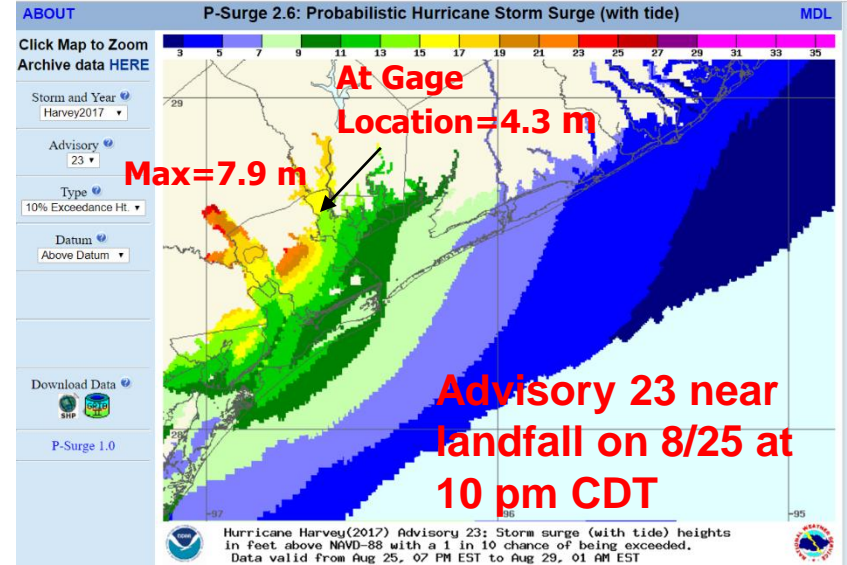

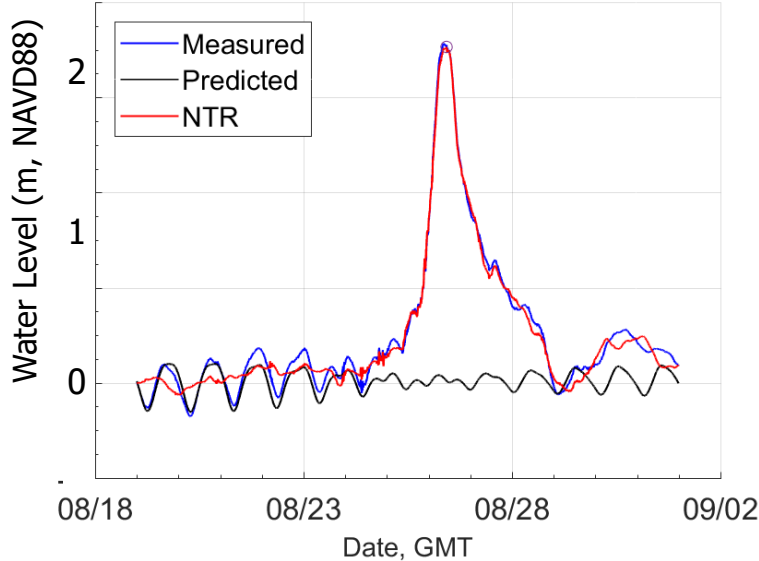

NACCS Surge Training Set Validation
18977 points overall mean RMSE = 0.11 m

NOAA P-Surge Forecast, 10% Exceedance, NAVD88 ft Hurricane Harvey August 2017

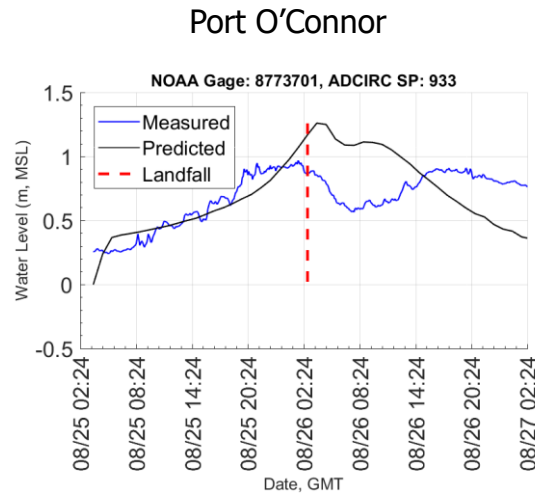

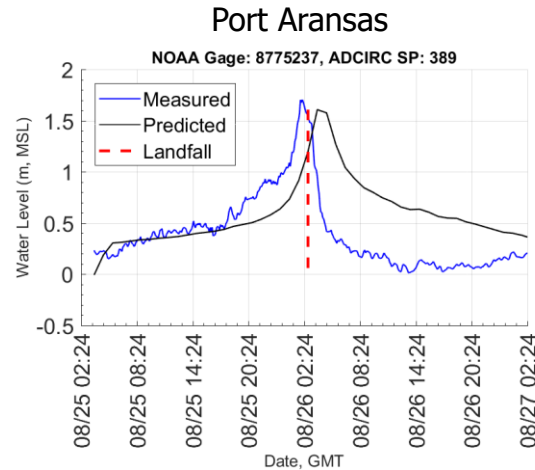

NOAA Water Level Gage: 8773259. Peak NTR = 7.0604 ft

Port Lavaca Gage

Advisory 16 error: +3.1 m
Advisory 23 error: +1.8 m

CHRP Example simulation for Hurricane Harvey Validation with Gages for Advisory 16 (36 hours from landfall)

Save Point 46 (29.0868°N, 91.0827°W)
Lon=-90.7°; $\theta=-41.0768^\circ$; CPD=59 hPa; Vf=20 km/h; Rmax=46.3 km

Save Point 415 (30.1388°N, 89.445°W)
Lon=-90.7°; $\theta=-41.0768^\circ$; CPD=59 hPa; Vf=20 km/h; Rmax=46.3 km

Save Point 563 (30.2934°N, 90.3004°W)
Lon=-90.7°; $\theta=-41.0768^\circ$; CPD=59 hPa; Vf=20 km/h; Rmax=46.3 km

Save Point 101 (29.3715°N, 89.1861°W)
Lon=-90.7°; $\theta=-41.0768^\circ$; CPD=59 hPa; Vf=20 km/h; Rmax=46.3 km

Save Point 600 (29.0548°N, 90.3566°W)
Lon=-90.7°; $\theta=-41.0768^\circ$; CPD=59 hPa; Vf=20 km/h; Rmax=46.3 km

Save Point 233 (29.66°N, 89.63°W)
Lon=-90.7°; $\theta=-41.0768^\circ$; CPD=59 hPa; Vf=20 km/h; Rmax=46.3 km

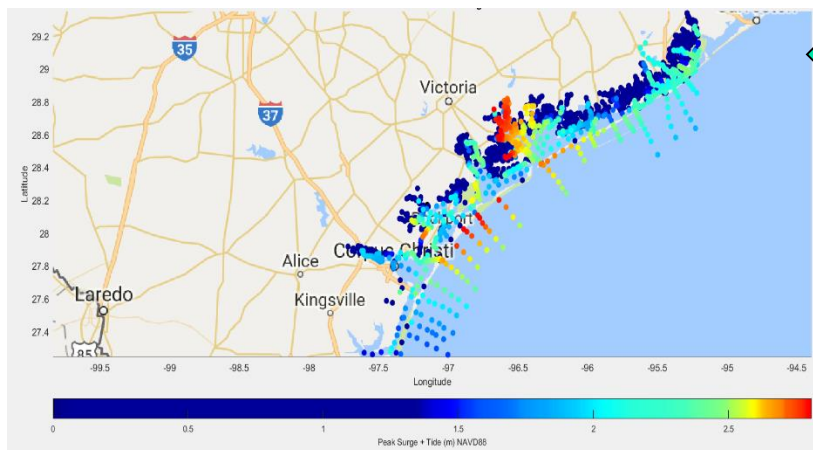

Save Point 81 (29.1548°N, 90.3004°W)
Lon=-90.7°; $\theta=-41.0768^\circ$; CPD=59 hPa; Vf=20 km/h; Rmax=46.3 km

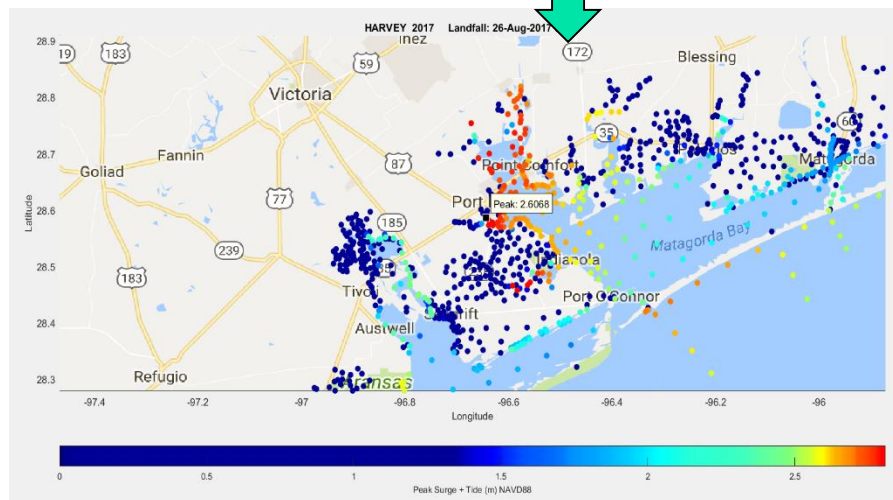

CHRP Surrogate Model Software Interface

Example simulation for Hurricane Harvey

Peak water level output

Zoom in and select a point

Get a plot of time series of surge+tide with landfall indicated

Surrogate Model Uses

- Forecasting in a second
- Import water levels into GIS/GE to illustrate risk
- Scenario analysis
 - Run historical storms with altered parameters
 - Run storms that have not occurred
 - Show the probability of each event separately
 - Varied sea level rise scenarios
- Can be used for risk assessment by running thousands of simulations in probabilistic simulations
- Can add waves, wind, rainfall
