

# 36TH INTERNATIONAL CONFERENCE ON COASTAL ENGINEERING 2018

Baltimore, Maryland | July 30 – August 3, 2018

*The State of the Art and Science of Coastal Engineering*

## LOADING ON PIPELINES DUE TO EXTREME HYDRODYNAMIC CONDITIONS

Presenter: Adrian Raul Simpalean, MSc student , University of Ottawa

Behnaz Ghodoosipour, PhD candidate, University of Ottawa

Jacob Stolle, PhD candidate, University of Ottawa

Ioan Nistor, Professor, University of Ottawa

Majid Mohammadian, Professor, University of Ottawa

# Motivation

The design of pipelines to withstand external hydrodynamic loading exerted on them requires a proper understanding of the external hydrodynamic forces.

The Trans-Alaska Oil Pipeline, is designed to move 20-ft laterally and 5-ft vertically.

36TH INTERNATIONAL CONFERENCE  
ON COASTAL ENGINEERING 2018  
Baltimore, Maryland | July 30 – August 3, 2018

# Motivation (Cont`d.)

A new topic in pipeline design has emerged recently due to the recent **extreme events such as tsunami and storm surges**. Typical examples are the 2011 Tohoku Tsunami in Japan and the 2012 Typhoon Haiyan in the Philippines.

# Introduction

Guidelines for Design of Structures for Vertical Evacuation from Tsunamis FEMA-P646 (2012) introduce different forces exerted on a body during a tsunami as drag and lift force:

$$F_d = \frac{1}{2} \rho_s C_d B (hu^2)_{max}$$

$$F_u = \frac{1}{2} C_u \rho_s A_f u_v^2$$

(Motley et al. 2015)

- **The 2017 ASCE7 Chapter 6, Tsunami Loads and Effects emphasized the need to investigate tsunami loads on pipelines** located in tsunami-prone areas.

# Objectives and novelty

- Novel study focused on **measuring and analyzing the forces caused by extreme hydrodynamic loading on submerged and above-ground pipelines due to transient flow conditions** by combining a comprehensive experimental study and detailed CFD simulations.
- New proposed values for the **resistance coefficient** in the case of a transient dam break flow for different relative gap ratios ( $e/D$ ).
- Recommendations from this study will hopefully be used for the **assessment and improvement of the current tsunami design guidelines**.

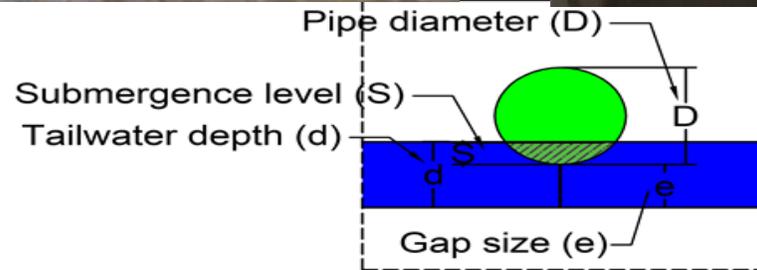

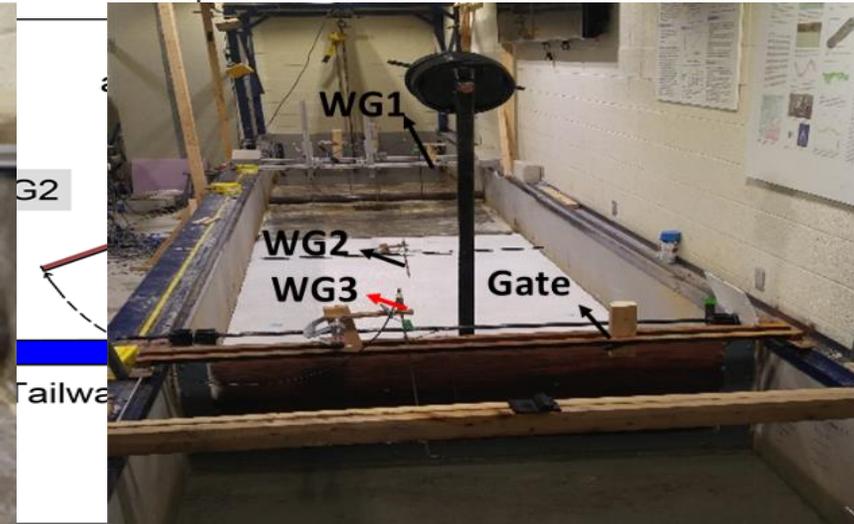

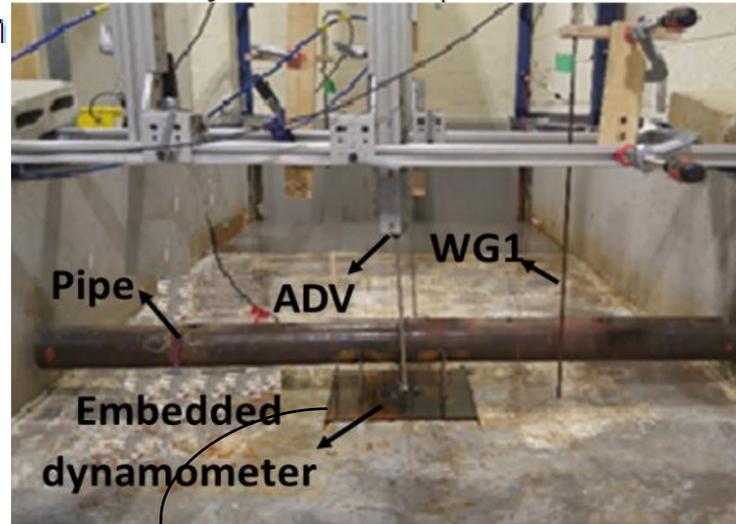

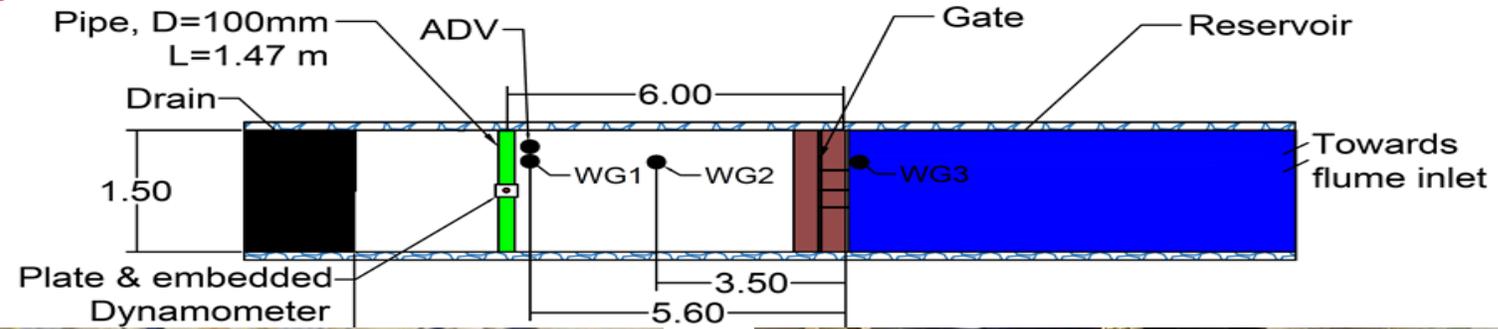

36TH INTERNATIONAL CONFERENCE  
ON COASTAL ENGINEERING 2018  
Baltimore, Maryland | July 30 – August 3, 2018

# Experimental setup

## Interface 6A68E

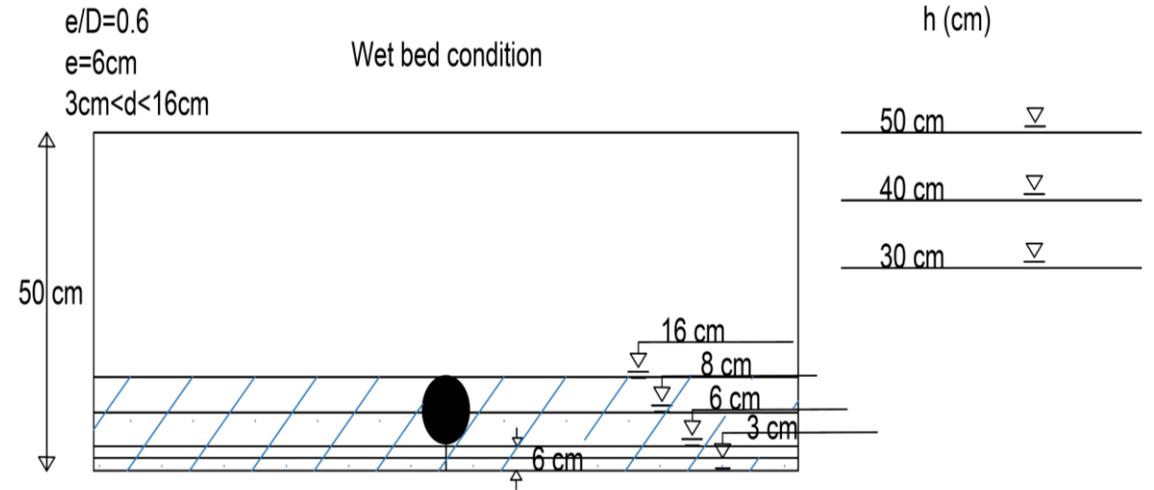

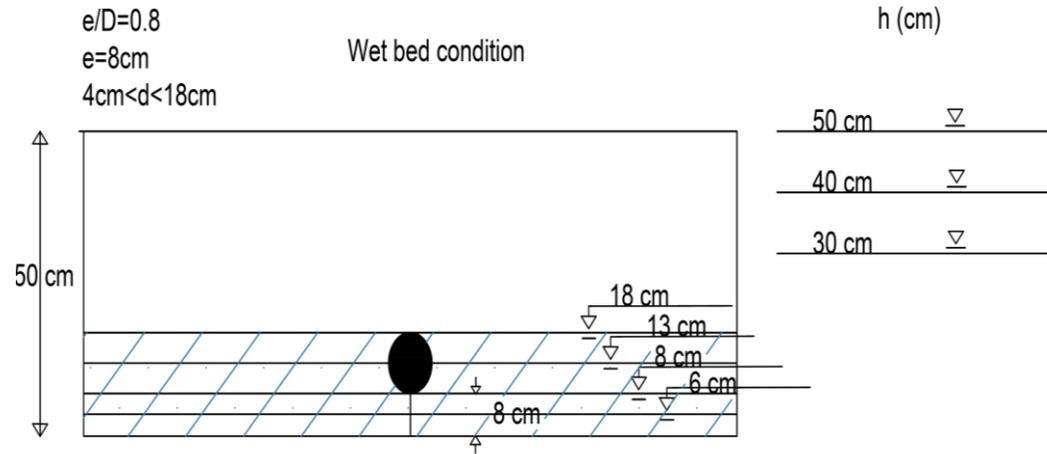

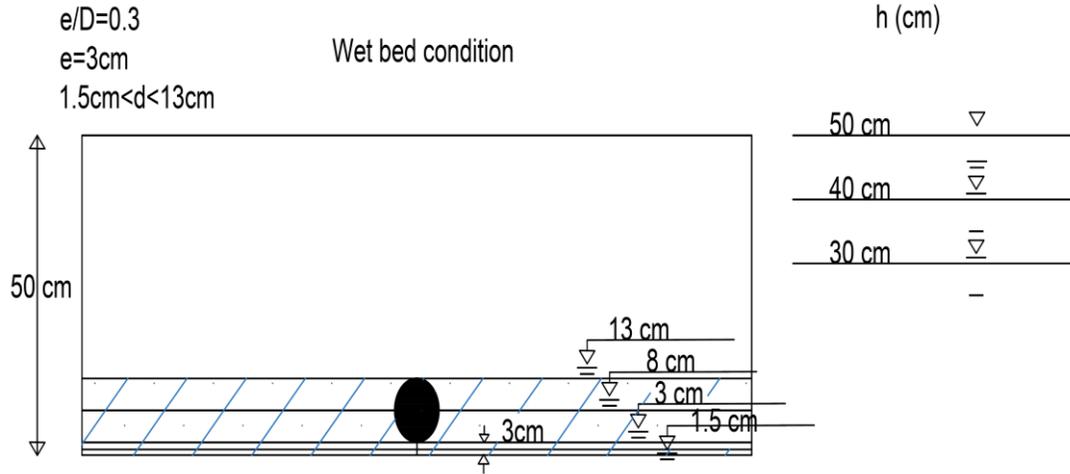

Max Forces:      Dimensions:

- $F_x = 10 \text{ kN}$
  - $F_y = 10 \text{ kN}$
  - $F_z = 20 \text{ kN}$
  - $M_x = 500 \text{ Nm}$
  - $M_y = 500 \text{ Nm}$
  - $M_z = 500 \text{ Nm}$
- $D = 83 \text{ mm}$
  - $H = 64 \text{ mm}$

# Experimental conditions:

$e/D=0.3, 0.6, 0.8$   
 $h=50, 40, 30$

Sample video:  
 $e/D=0.3$ ,  $h=40$

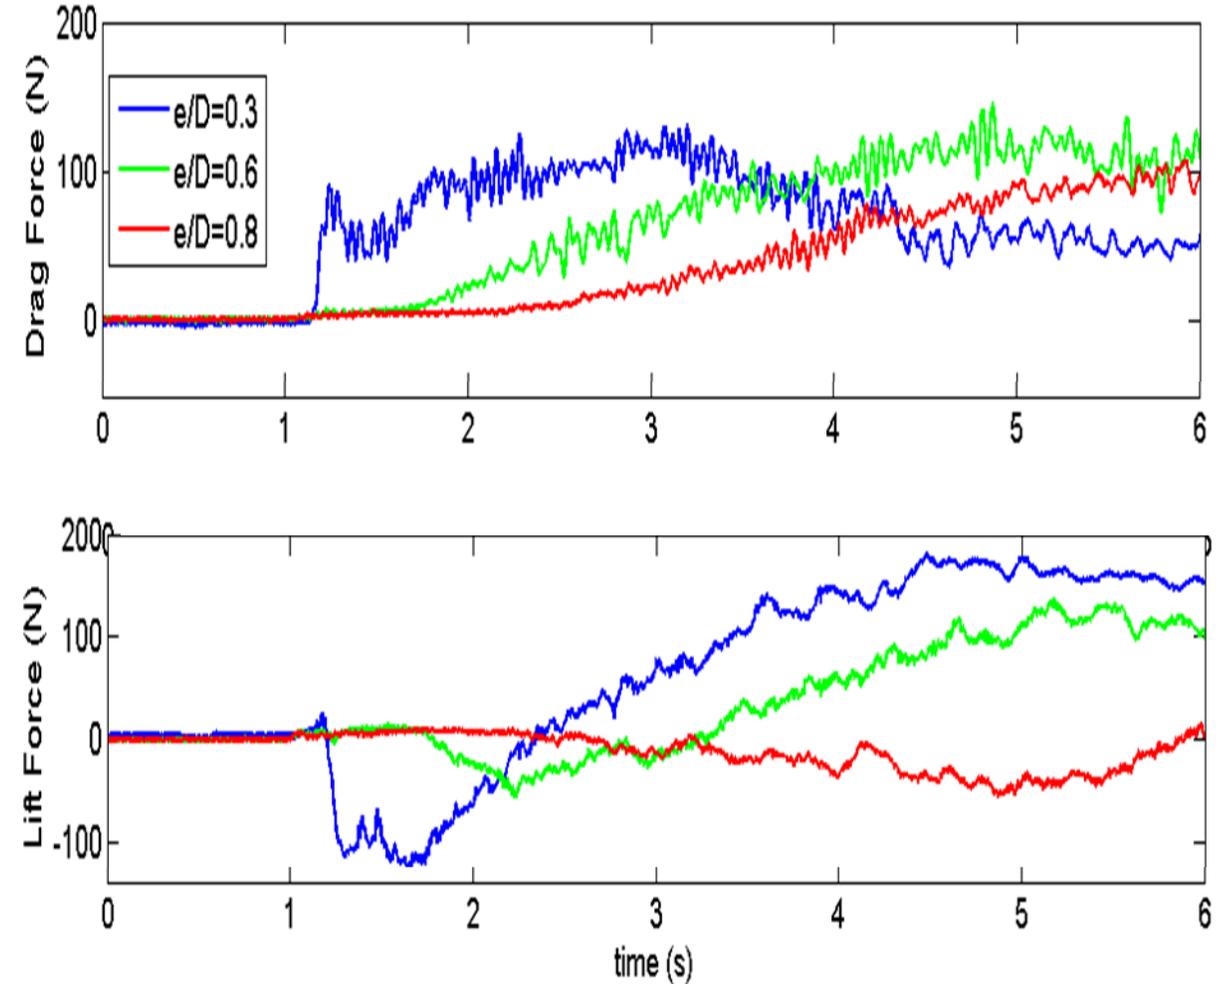

# Force components

## Dry bed conditions and varying $(e/D)$ ratio

- For  $e/D=0.3$  an impulse force as well as run-up force are noticeable while for  $e/D=0.6$  and for  $e/D=0.8$  no distinct impulse peak was noticed.
- Lift force is larger for smaller  $e/D$  values.

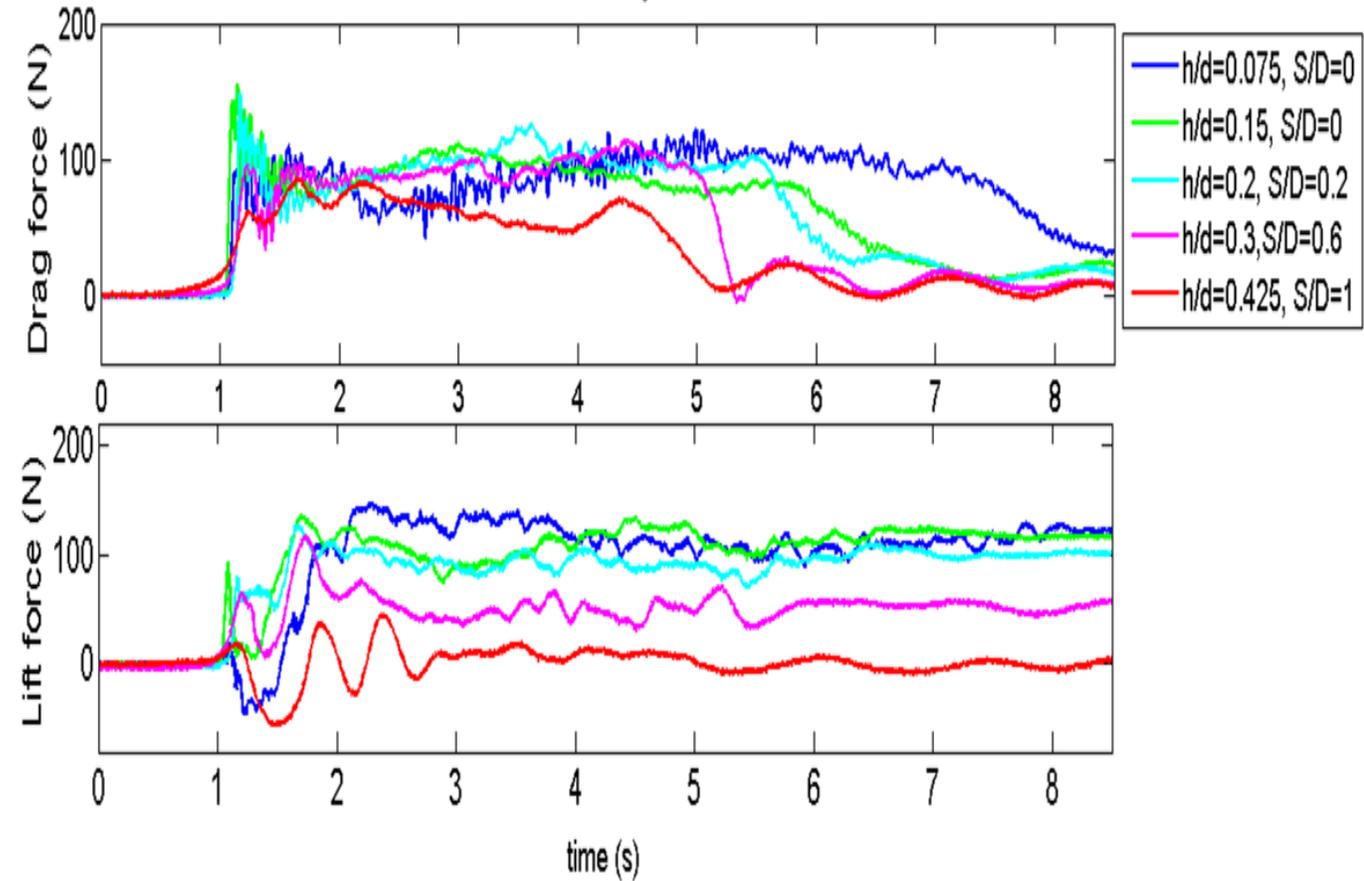

# Force components

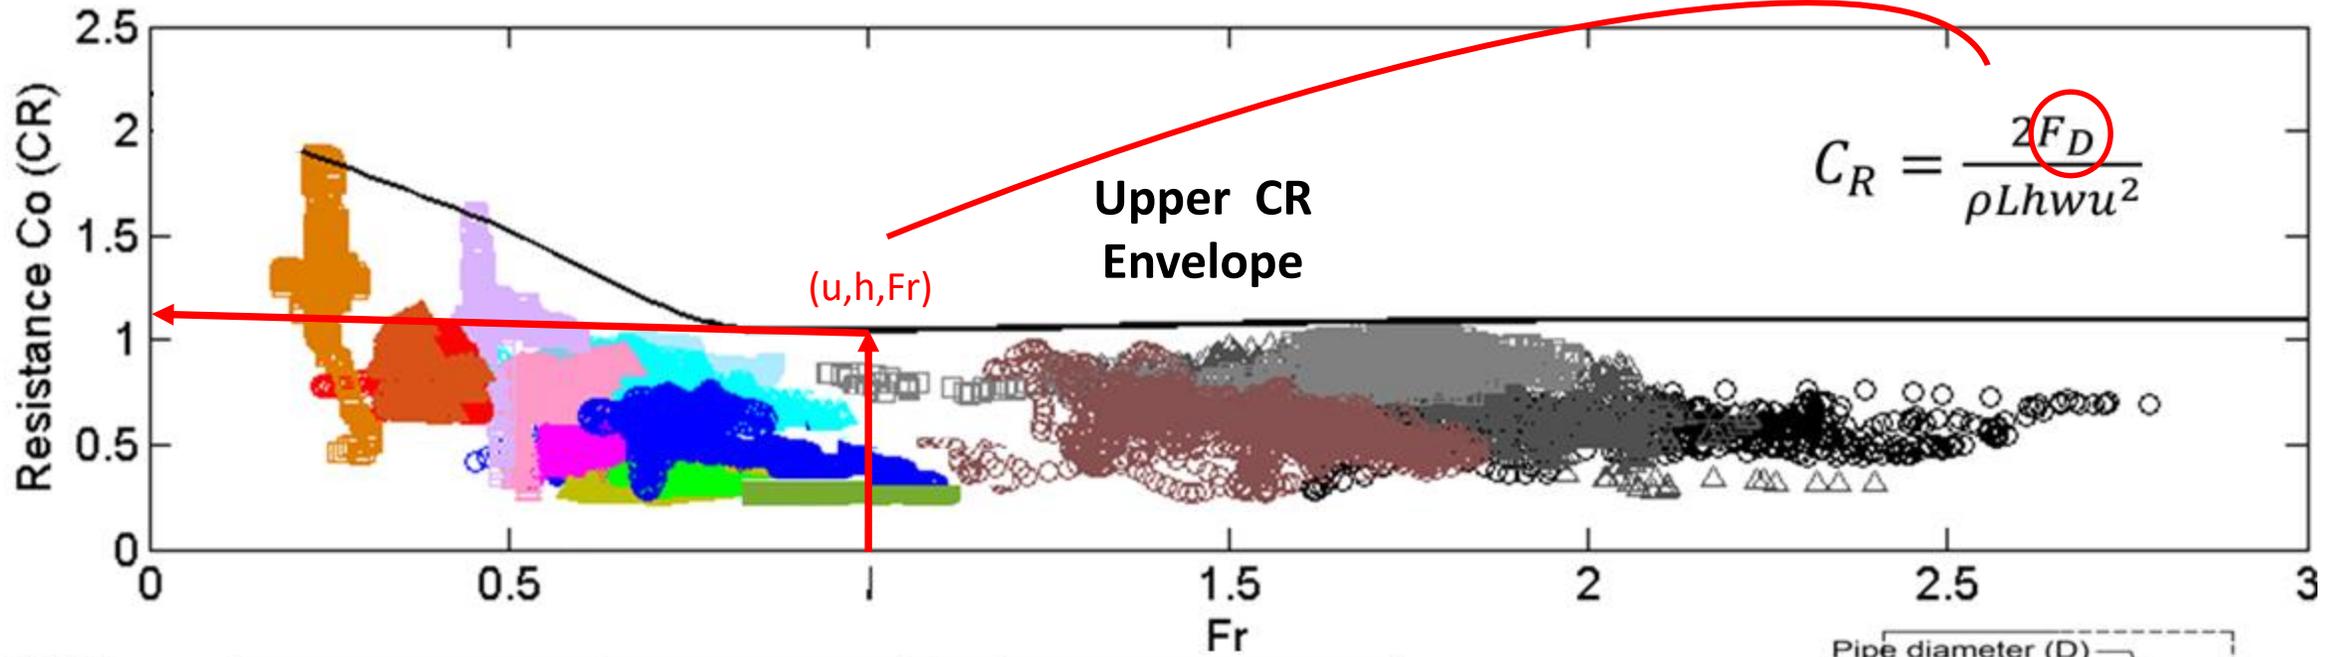

## Wet bed conditions and varying (e/D) ratio

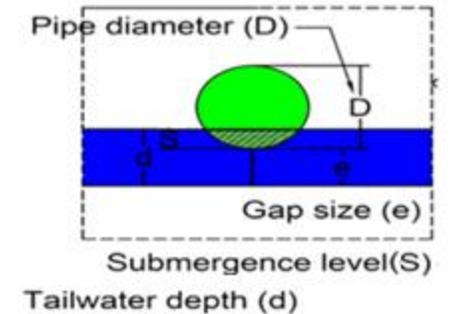

- Smaller level of pipe submergence results in larger impulse drag force.
- Lift force decreases by increasing the level of pipe submergence.

# Resistance Coefficient

S/D=0	○ d/h=0.06, wet	△ d/h=0.075, wet	○ d/h=0.1, wet
S/D<0.2	○ d/h=0.12, wet	△ d/h=0.15, wet	□ h=30 cm, Dry
0.2<S/D<=0.5	○ d/h=0.16, wet	△ d/h=0.2, wet	△ h=40 cm, Dry
0.5<S/D<0.8	○ d/h=0.24, wet	△ d/h=0.3, wet	○ h=50 cm, Dry
S/D>=1	○ d/h=0.34, wet	△ d/h=0.425, wet	□ d/h=0.2, wet
			□ d/h=0.26, wet
			□ d/h=0.4, wet
			□ d/h=0.56, wet

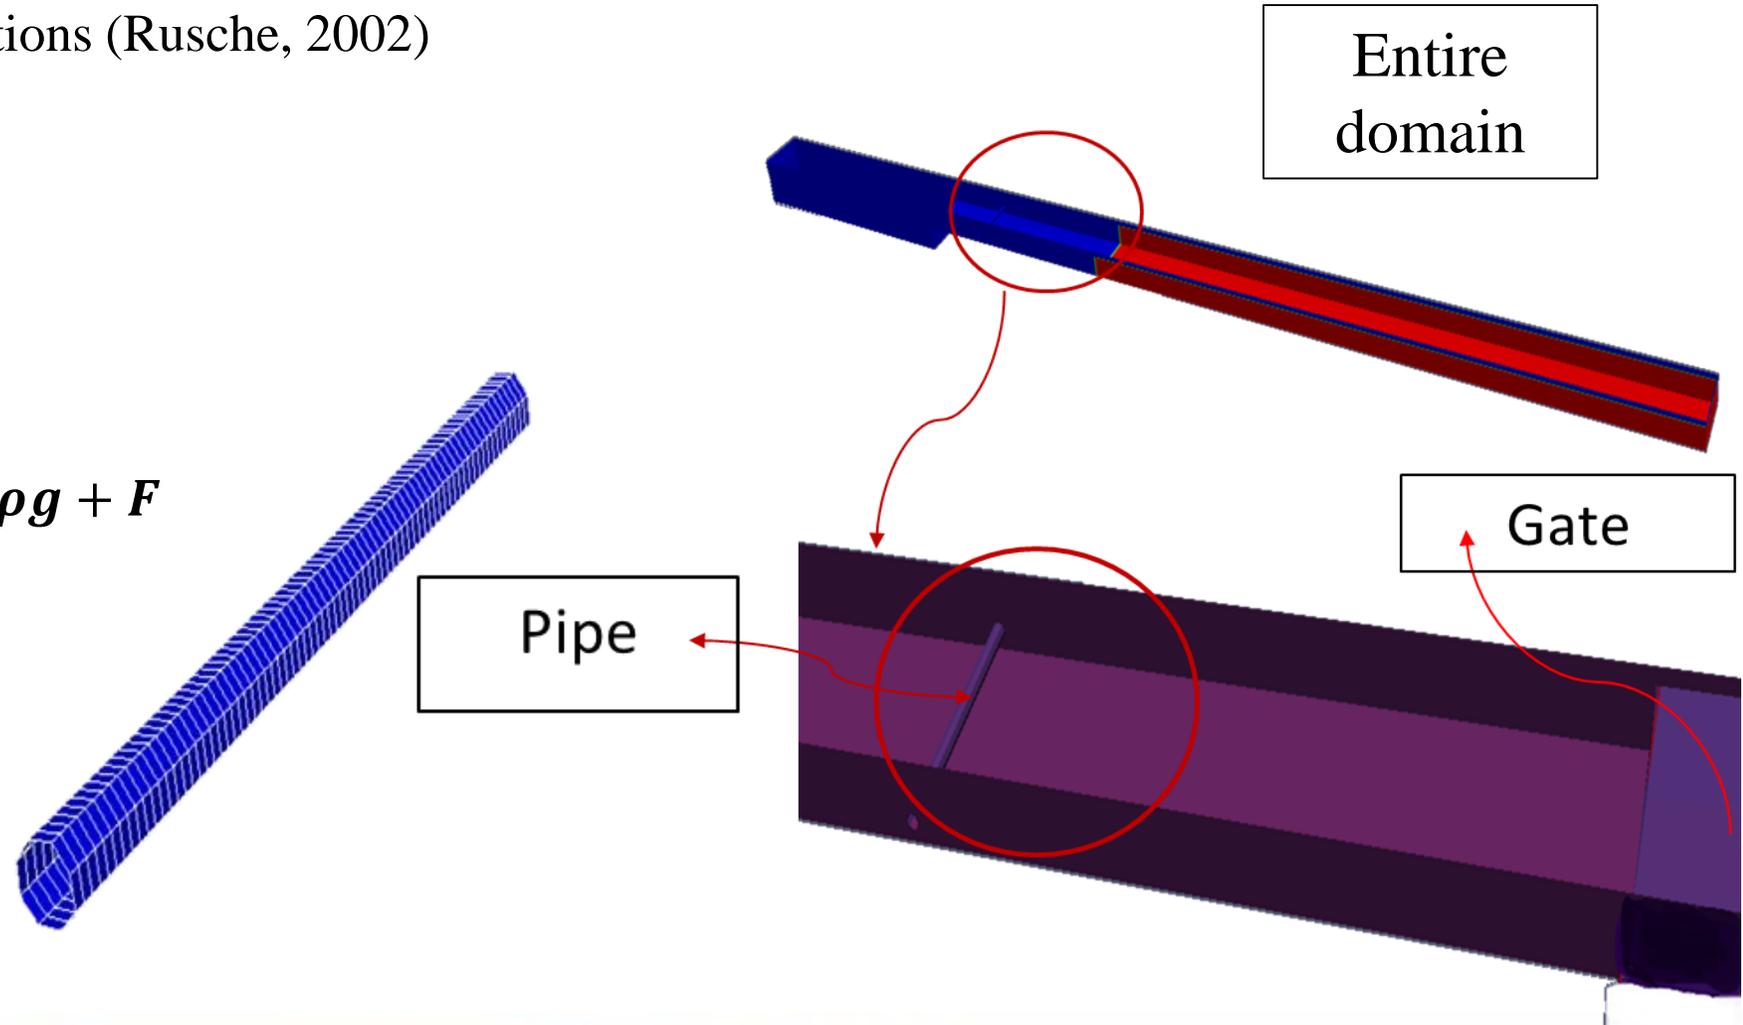

# Numerical model

**OpenFoam** CFD Modeling tool - uses the Finite Volume Method to solve the 3-D Navier-Stokes equations (Rusche, 2002)

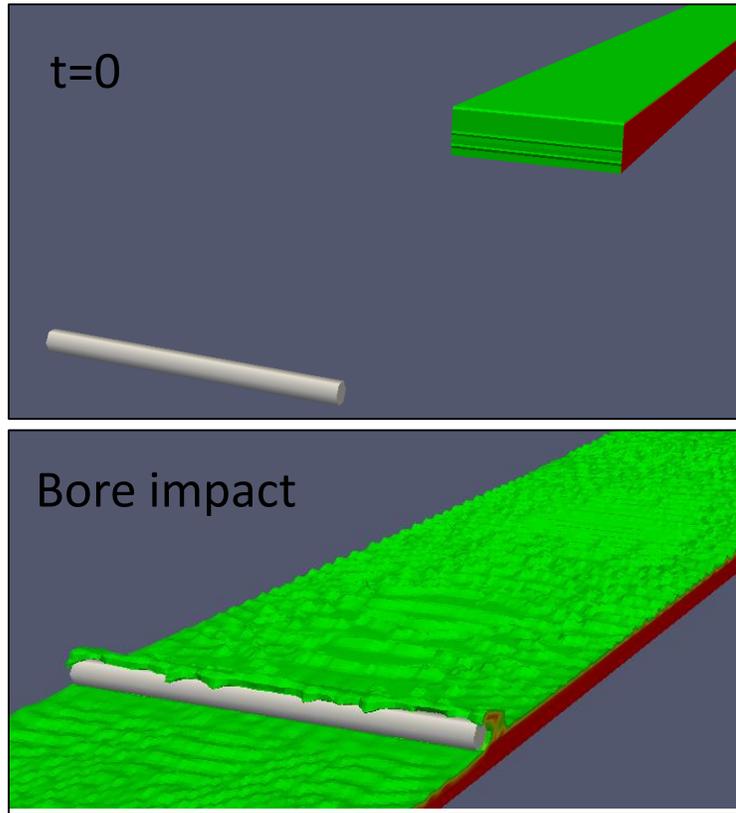

$$\nabla \cdot U = 0$$

$$\frac{\partial \rho u}{\partial t} + \nabla \cdot (\rho U U) = -\nabla P + \nabla \cdot \tau + \rho g + F$$

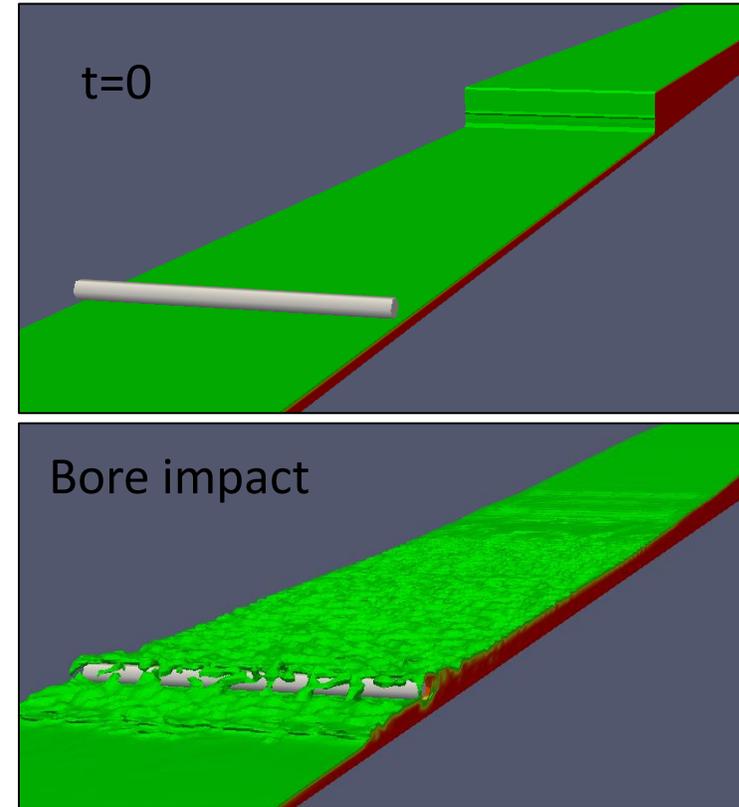

# Numerical model results - water level

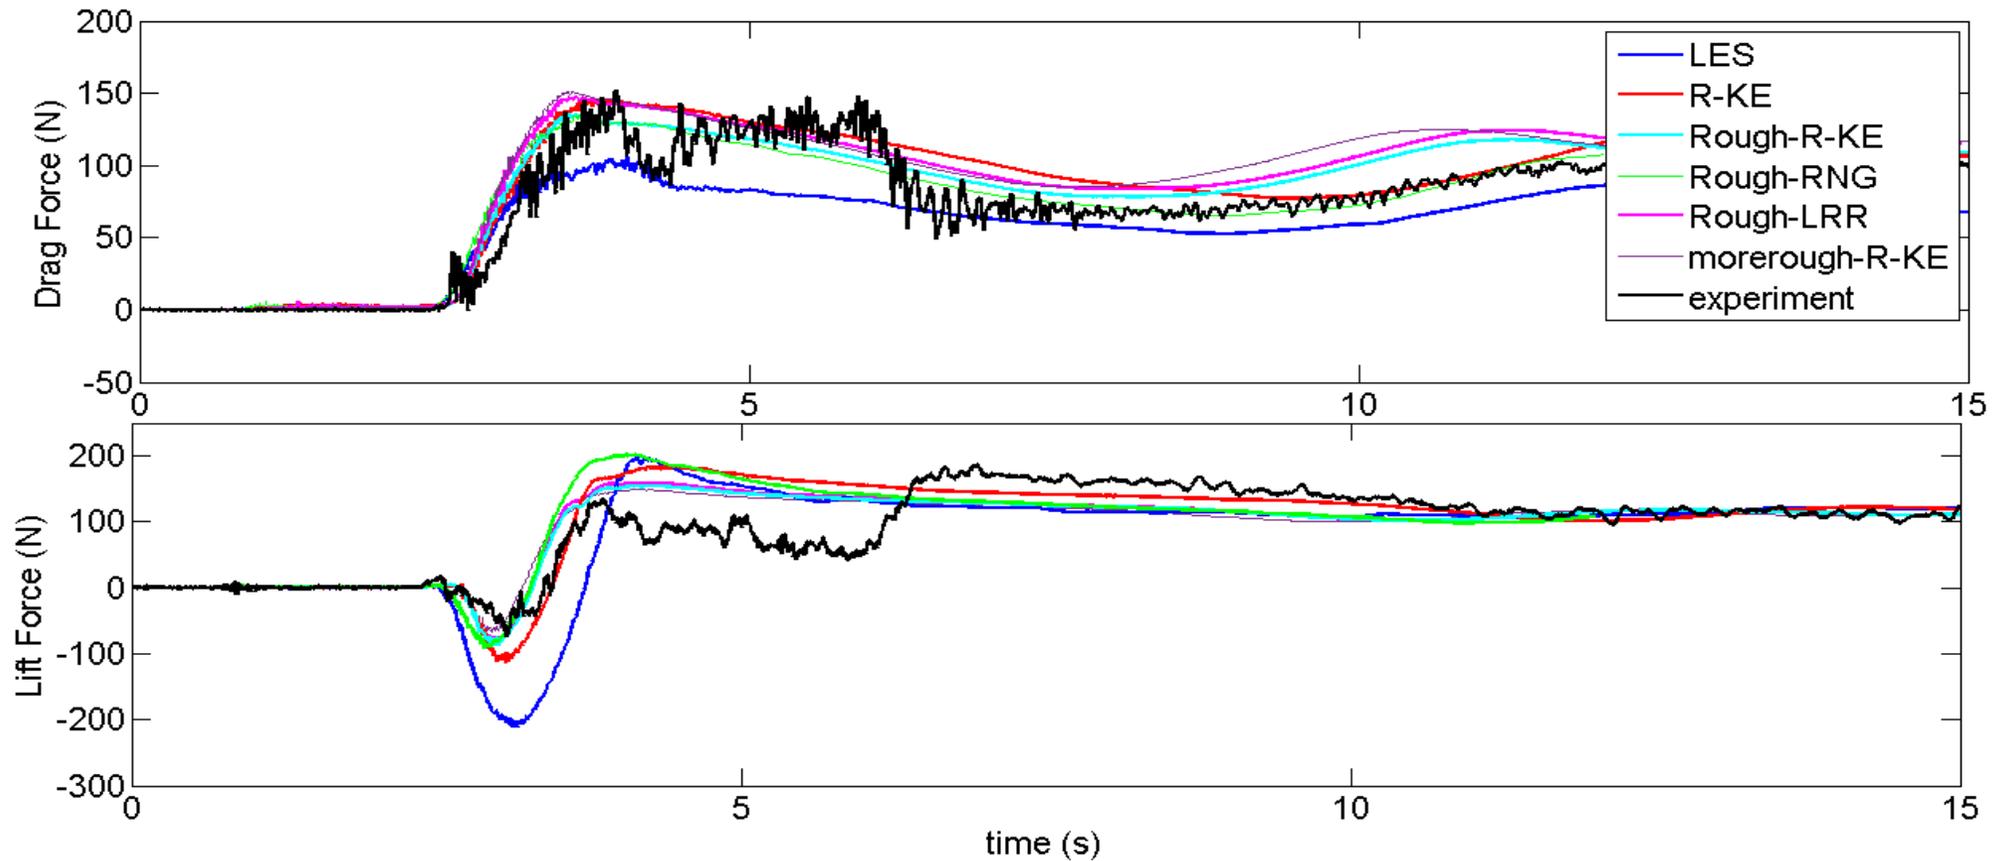

## Dry bed condition

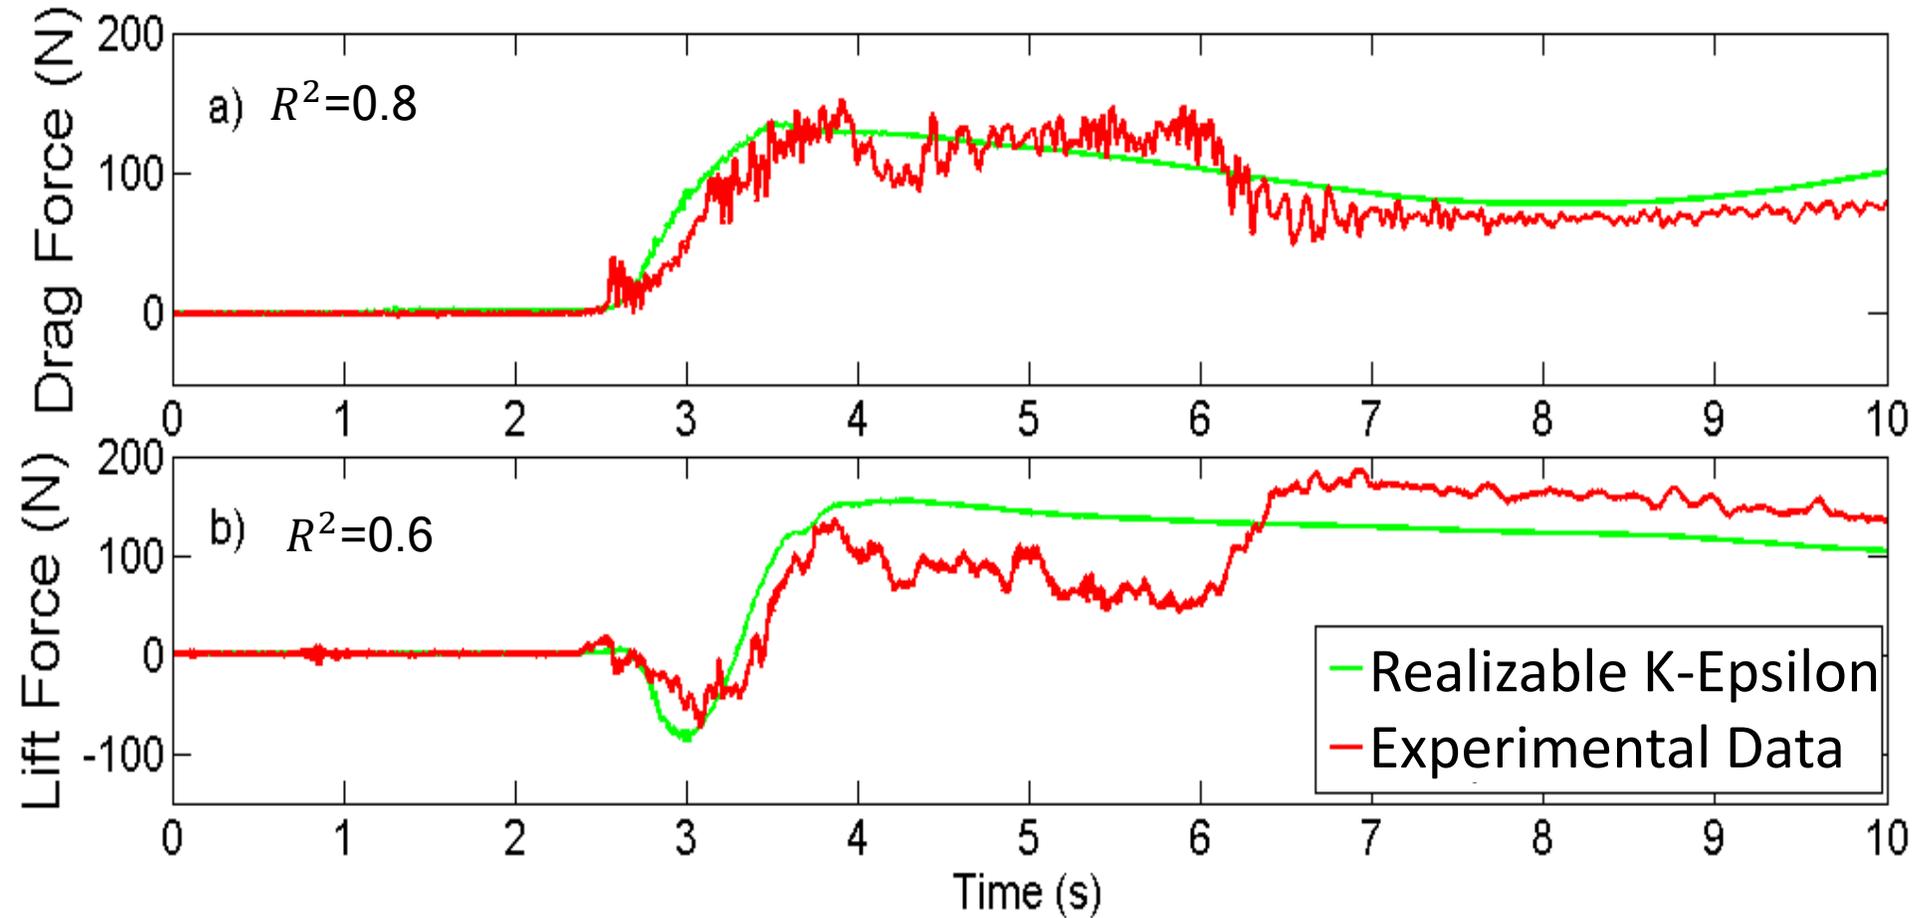

## Wet bed condition

# Effect of turbulence models & Effect of surface roughness

# Experimental and numerical results-force components

# Conclusions

## Force time history

- **Dry bed condition:** Beginning of bore surge: Larger drag force for  $e/D \leq 0.3$ .
  - After the pipe got fully submerged : Smaller drag force for smaller  $e/D$  ratios due to vortex shedding suppression. Larger lift force magnitudes for smaller  $e/D$  ratios during the entire time history due to the asymmetry in pressure distribution in presence of plane boundary.
- **Wet bed condition:**
  - Smaller initial level of submergence ( $S/D < 0.3$ ): larger impulse force.
  - Submerged pipe ( $S/D = 1$ ): No impulse lift force was observed.

## Resistance coefficient

- **Wet bed condition:** Increase in initial level of submergence  $\Rightarrow$  Resistance coefficient increase
- **Dry bed condition:** Increase in relative gap ratio value ( $e/D$ )  $\Rightarrow$  Resistance coefficient decrease
  - Study suggests using **resistance coefficient** values of  $(1.2 < C_R < 2)$

## Numerical model

- Comparing results between different RANS and LES turbulent models with those obtained from experimental tests showed that the **RANS** models reproduced most accurately the dam break wave flow field.
- The **realizable K- $\epsilon$**  model results provided the most accurate results compared to other RANS turbulence models.

# Other Pipe configurations

**36TH INTERNATIONAL CONFERENCE  
ON COASTAL ENGINEERING 2018**  
Baltimore, Maryland | July 30 – August 3, 2018

# Pipe with angle to the flow: $\theta=30$ & 45

$\theta = 45$

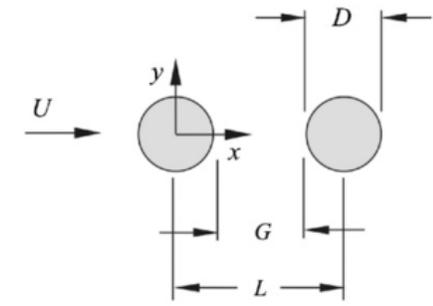

$\theta = 30$

# Tandem configuration

$L=1D$  &  $2D$

$L=1D$

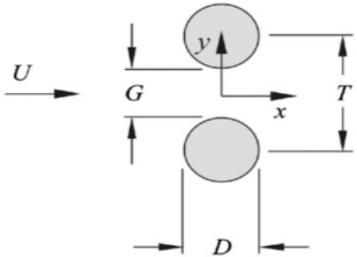

$L=2D$

# Side by Side Configuration

T=1D & 2D

T=1D

T=2D
