 - Ameland ebb-tidal delta

SEAWAD: Sediment supply At the Wadden Sea ebb-tidal Delta

- Investigate feasibility and efficiency of mega nourishment on ebb tidal delta and obtain system knowledge
- Interaction of waves, currents, sand, and fines
- Field Campaign September 2017: Ameland Inlet

PhD topic:

Investigate influence of tidal currents on wave-induced sediment transport

Here:

First analysis of observed sediment concentration will be shown:

1. Time averaged
2. Instantaneous

Field campaign

- September 2017
- 5 instrument frames and 8 pressure sensors
- Drifter deployments
- Sediment and water samples

H_{m0} [m]

T_{m01} [s]

η [m]

v [m/s]

Field campaign - frames

- 3x ADV, ADCP upward and downward: velocity
- 4x OBS: concentration
- LISST: particle size distribution
- SONAR: bed forms
- CTD: conductivity, temperature, density

Processing of OBSs

- Optical BackScatter measures concentration
- 20, 30, 50 and 80cm above bed
- Calibration using locally retrieved sediment from the bed

Processing of ADVs

- Acoustical Doppler Velocimeter measures velocity
- 50cm above bed
- Filtered and despiked

Sediment suspension – time-averaged

c [g/L]

v [m/s]

H_{m0} [m]

Sediment suspension – time-averaged

Sediment suspension – time-averaged

Sediment suspension – time-averaged

1: waves and currents -> no suspension

2: no waves, no currents -> suspension

So suspension cannot be explained by hydrodynamics only

Sediment suspension – time-averaged

Sediment suspension – time-averaged

c [g/L]

**Export of fines during ebb
disturbs the OBS signal**

Sediment suspension – time-averaged

- Export does not happen every tide
- Highest concentration does not correspond to highest waves

Hypothesis:

- Export only if there were significant waves in the past days
- Fines stirred up by waves inside the basin and transported out of the basin by ebb tide
- Amount of exported fines is not a function of local and present conditions but of larger scale (basin and weekly) conditions

Sediment suspension – instantaneous

- Case selection:
 - Short duration (no changes in sediment and water mixture)
 - Storm conditions
 - Low amount of fines
- Zero-down-crossing analysis on near-bed velocity to specify waves

Sediment suspension – instantaneous

- Case selection:
 - Short duration (no changes in sediment and water mixture)
 - Storm conditions
 - Low amount of fines
- Zero-down-crossing analysis on near-bed velocity to specify waves

Sediment suspension – instantaneous

- Case selection:
 - Short duration (no changes in sediment and water mixture)
 - Storm conditions
 - Low amount of fines
- Zero-down-crossing analysis on near-bed velocity to specify waves
- Waves normalised by wave period

U_n [m/s]

Sediment suspension – instantaneous

- Case selection:
 - Short duration (no changes in sediment and water mixture)
 - Storm conditions
 - Low amount of fines
- Zero-down-crossing analysis on near-bed velocity to specify waves
- Waves normalised by wave period and phase averaged

U_n [m/s]

Sediment suspension – instantaneous

η [m]

U_n [m/s]

c [g/L]
at $z = 80\text{cm}$

c [g/L]
at $z = 50\text{cm}$

c [g/L]
at $z = 30\text{cm}$

c [g/L]
at $z = 20\text{cm}$

t/T

Sediment suspension – instantaneous

η [m]

U_n [m/s]

c [g/L]
at $z = 80\text{cm}$

c [g/L]
at $z = 50\text{cm}$

c [g/L]
at $z = 30\text{cm}$

c [g/L]
at $z = 20\text{cm}$

t/T

Sediment suspension – instantaneous

- Suspension beneath wave crest and wave trough
- Close to the bed: suspension trough > suspension crest
- Higher in the water: suspension crest > suspension trough
- Difference in vertical distribution of turbulence?

Conclusion

- Strong variations in mixture of sand and fines over the tidal cycle complicates using OBS concentration
- Difference in suspension is observed between wave crest and trough in intra-wave analysis

Follow up:

- Extension to other frames
- Look at acoustical backscatter combined with OBS and LISST data
- Check velocity profile close to bed with ADCP to further investigate suspension events
